

the same time as ethereum. All of this is possible without compromising the hashrate of the latter.

Obviously, mining the dual coin at full potency will have an impact on the ethereum hashrate. Therefore, you need to optimise the dual coin's strength and intensity, dropping it to the point where it has no impact on the cryptocurrency hashrate.

The dual coin is configured to mine extensively, and many GPU cores are dedicated to that activity. Indeed, it is required for solo mining as well,

Even smartphones can mine for crypto

and it must be set to 6! This is an essential component because it solely depends on the GPU series. The GPU core is the only visible difference between the RX 570 and RX 580 series. The RAM on both cards is nearly identical, so there is little change in ethereum hashrate, but the GPU core seems to be the big variation.

The RX 580 series can manage roughly around -dcri 25. However, don't go beyond that, else, your ethereum hashrate will suffer. The ideal -dcri for the RX 570 series is around 19-22. This range, however, may vary as you test with some other cards. Starting with -dcri 10 is the appropriate way to kick start. Then press "+" or "-" on your keyboard to increase or reduce -dcri by a factor of one. Dual mining is possible on the RX 570 series to acquire a greater hashrate on ethereum.
