

there. You store your data on a hard drive or solid-state drive, which you can use to recover data from when needed. The external storage device stays with you and is instantly accessible.

In the second form of offline backups, the data storage part remains the same, meaning that your data is stored on an external storage device instead of being loaded onto a server, but the thing that changes is the storage location of the device and the eventual accessibility. When using this form of offline backup, the storage device, instead of being stored in the same location, in many cases connected to the same network (network assisted storage), the storage device, is moved out of the original location of the backup creation and is stored at a faraway facility.

External storage is the best. Change my mind

Due to the geographical limitations/distance between the place of creation and storage, there is a lack of data accessibility, meaning that it will take time for you to get the data back in case of any failure or infection of the original data source. This method of data backup is beneficial in two very important ways.

The first one is that it protects against any physical hazard like fire or any other act of nature, which could affect both the original data source and backup if they are in the same place. The second way in which it
