

tems and then, without letting anyone notice, take it to another location, which might be thousands of miles away from the original location and resurface it there, sending it to the server of the service in use from that location. What this does is, it creates a perception that data is coming from another location, which is completely different from where it originated in the first place.

But what is the use then?

The way we explained VPNs above might have made it seem that VPNs are nothing but location cloners. But they actually do much more things than just faking your location.

When the data is picked up from the source computer, it is then scrambled into several bits and pieces, which are then encrypted and transferred over several channels to the other end, where the bits and pieces are decrypted and combined to yield information.

While all of this is happening, two main things of yours are protected. number 1 is the IP address and location of your computer system, and number 2 is the information that you are sending is prevented from being siphoned off, while it is being transferred to the server of the service that you were sending it to. The location of the device that you are using is hidden, because the service is receiving it from effectively a computer that is not owned by you.

All about deception
