

when the people around you are acutely interested in seeing the content that is being displayed, and you would not want them to see your chat or any other content that is displayed on the screen.

In either of the cases, all hope is not lost though. There are some solutions and tricks that you can put to use, to make sure that your data is not being looked at and meticulously noted down, and then having your million-follower Instagram account hacked into or bank balance drained. While it can be prevented by not accessing private information or entering it in public, there are certain people for whom it is more than that. And, irrespective of the category or situation you fall in, you should seriously look at the solutions that we suggest.

They protect your screen and your privacy

Privacy screen protectors are specially designed screen protectors that make sure that only when the screen that they are attached to, is held at a certain angle with respect to the viewer's eyes that the information is seen. You have to be looking head-on at the screen that has a privacy screen protector on it to be able to see anything that is being displayed.

The way that they work is, by narrowing the field of view of the screen that they are applied to. The material is such that it allows the light coming from the screen to pass through at certain angles. To understand the physics of it, crack open the dmystify from last month, where we covered Optics extensively. The angle of light is limited to around 60 to 90 degrees meaning that anyone beyond that angle would not be able to see the screen and would rather be greeted with a black blank screen.

The effectiveness of these screen protectors or films that can be applied to different screens depends a lot on the way that they are made. Two major types are present in the mass market. The ones with a technology called 'micro louvre' and the generic ones which are nothing but your normal screen protectors or films, but with a darker tint.

As you would have already made out by now, the ones utilizing the micro louvre technology are better, because they have different layers, put together after a lot of testing and experimentation. They provide better visibility to the user and the peepers get nothing from the screen that they want to get information from. Apart from this, they are also touted to do much more, like blocking the blue rays, and relieving eye strain, both of which are a bonus for the users since most of us end up using our devices for extensive periods of time.
