

Factor authentication code, any login attempt into the account would be blocked completely.

Ensure home Wi-Fi hygiene

One of the most used and secure networks in one's life on the internet is their home Wi-Fi network, and this arguably should be the most secured place that you can access the internet from. But, that secured facility might have some unwanted entities roaming around, peeping into your network traffic and sometimes redirecting it to places that you might not want it to go.

To ensure that nothing of this sort happens, here are a few things you can do:

- Make sure that all the devices that are connected to the network are recognised by you. If you find any unrecognised device on your network, just block it.
- Change your password regularly and don't have it as 'password'. That trick is ages old. Use a password manager to suggest to you what you can have as the Wi-Fi password.
- Check the data usage and traffic regularly. For this, users can either take help from your ISP or use services like GlassWire. Be on the lookout for any unusual spikes in data use, and look for any anomalies that stand out. If you find any, it is time for a more thorough check.

Check twice, cut once they say. We say verify twice, login once
