

- Use a reputable ISP. This is something that is often overlooked by users. Before going ahead with using a specific local ISP, make sure to run sufficient reputation and other background checks, because there have been cases where ISPs have been the ones who have punched holes in their networks, allowing the bad people to come in.
- Ensure that devices connected to your network are secure themselves. If even one of the devices is not secured, your entire network might be at risk.

Spend money where it matters

There are free workarounds for everything on the internet. But it is no hidden fact that everything comes at a cost. There are some places where you should spend the bucks, because it might save you a lot of unseen hassle and risks. Have a look at our checklist and make sure that at least in these places, you invest your money in. Yes, we say invest because, you are using your money to ensure your safety on the internet.

1. Password Manager:

Subscribe to a proper password management service. Many of them like LastPass, do sponsorships for different creators and you can use their codes to get some of the best services on the cheap. Password managers are fast, hassle free and in almost all cases secure. It is better than the 'password protected excel sheet' that literally a 10-year-old with basic computer knowledge can break into.

2. Your ISP:

If you are not sure about the reliability in terms of data handling of an ISP, and their plan looks too good to be true, it often is. Always go with a reputable internet service provider, even if it might mean you have to shell out a couple of extra bucks of your hard earned money.

3. Software Licenses:

Yes. It is a thing. When you are using a pirated copy of a software, you are not only indulging in what is an illegal activity, where nothing you do is owned by you, but also potentially exposing yourself and your data to the 'bad people' on the internet. Something as simple as a wallpaper engine that you downloaded a pirated copy of, might be laced with programs that would take your data and dump it off in some reserve, where who knows how it is used.
