

When on there, sensitive data like passwords and usernames are siphoned off by the attacker, who after collecting the needed information from the target demographic shuts down the network and moves on to another location. The reason that these attacks are so successful in modern spaces like offices, because in many cases access points sharing the same name are spread across, to ensure proper long-range connectivity. So, when another signal with the same SSID comes in, people fail to notice more often than not. This attack can also be configured to make sure that the data is being transmitted over the legitimate network, but the network is being watched.

The most common implementation of this attack is in the form of a captive portal attack. Here, first a clone network is created, and then the original network with a denial-of-service attack is shut down. This causes the computer systems and other devices on the network to connect to the bogus network, which has been set up by the attacker. There are other forms of this evil twin attack also, which if executed correctly can enable the attacker to gather data over a long period of time while remaining unnoticed.

The only way in which you can protect your network from falling prey to an evil twin attack, is by constant monitoring. If your trusted network suddenly drops and you notice an open network of the same name, never connect to it. Secure all the devices on the network and for diagnosis, use the ethernet cable from the router to connect safely to the internet.

They simply re-route and steal your information

For the creators

After the onset of the pandemic, the internet has seen a rise in creators posting their content online. They are also at risk, especially the ones who work with video content.
