

Read up, as much as you can

through online searches or at your local library. You can also come across past studies and experiments that can aid your thinking and conclusions.

In this scenario, you might want to start by looking through existing scientific studies on animal reactions to music. Look for research that looks at animal behaviour in relation to art or domestic animals that are directly affected by music to uncover relevant material.

3. Form your hypothesis.

A hypothesis is an educated guess that attempts to address a systematically testable question. Your hypothesis should also include predictions that you can test through research and experimentation.

For instance, based on your research, you begin to fine-tune your predictions about what will most likely occur: “If I play classical music in the room, will the rats come out of their holes and start dancing like Jerry did in an episode of Tom and Jerry.” Perhaps, the rats

will leave the room (and hopefully, the house) if I play heavy metal songs.”

Put forth your hypothesis to be tested
