

Iterate your experiments in view of your new hypothesis

you see that, contrary to your expectations, nothing happened. More specifically, the genre of music played had no effect on the rats' reactions.

As a result, you change your hypothesis to indicate that the rats' reactions will be determined by the volume of the music. You repeat the experiment, this time playing classical music at low volume and then at high volume. When the music is quiet, the rats stay in the room; when the music is loud, they depart.

6. Assess the findings and develop a conclusion.

You can now assess the results of your experiment to see if they support your hypothesis.

Drawing a conclusion entails determining whether or not what you predicted occurred. If this does not occur, construct a new hypothesis, return to step four, and conduct a new experiment to test your new theory.
