

time to decide which food to eat or limited information to decide which house to buy).

People are compelled to rely on heuristics, or rapid mental shortcuts, to help them make judgments as a result of their limited resources. Tversky and Kahneman sought to know more about the unique biases that come with this type of assessment and decision-making. To do so, the two researchers used a research paradigm in which participants were given with a reasoning issue with a computed normative response (they used probability theory and statistics to compute the expected answer).

The actual responses of the participants were then compared to the prepared solution to uncover the consistent mental aberrations. The researchers were able to detect several norm breaches that occur when our minds rely on these cognitive biases to make decisions and judgements after conducting several tests involving a large number of reasoning issues.

List of biases

There are literally hundreds of biases but they can be broadly classified into a much smaller group. We're going to list out some of the most common biases that can plague your research efforts.

Availability Bias

The availability bias (also known as the availability heuristic) is the propensity to believe that examples of things that come to mind easily are more common than they actually are.

How we perceive the world around us
