

cessed, whereas stimuli that don't fit into one of these two categories may be overlooked.

The mental workload theory states that if we devote a large portion of our brain's mental energy to one input, we will exhaust our cognitive resources and will be unable to process another stimulus at the same time.

Similarly, some psychologists describe how we pay attention to different stimuli with varied levels of attentional capacity, which can alter our ability to comprehend many inputs at the same time.

To put it another way, an experienced driver may be able to observe that automobile veer into the lane because they are using fewer mental resources to drive, whereas a novice driver may be using more resources to focus on the road ahead and therefore unable to process that car swerving in.

How to fight biases

Because our biases are so deeply ingrained, it might be difficult to overcome them. In fact, according to one study, people can admit to having a bias but still utilise it to make decisions, then claim to be impartial in their assessment.

So, do your best to avoid biases in your own thinking and decision-making by taking your time, questioning your own thoughts, intentions, and motive, consulting others, and avoiding these frequent thinking pitfalls.
