

Systematic learning

In the age where information is so readily available, the concern is no longer about getting to know about something. It's about knowing something 'properly'. The entire act of researching is all about asking the right questions and digging deep enough to unravel the truth.

There's no fixed method for performing research since it applies to every concept known to us. And given how massive the spectrum of topics is, the techniques that need to be applied vary vastly. What we're focused on is the basics of research. A generalised set of principles which can be easily applied to practically any topic and will help you get the knowledge that you seek. A little bit of Googling will throw up numerous programs and algorithms for performing research. From 5-step processes to 15-step algorithms, there's an approach tailor-made for each domain of knowledge. We've distilled that down to just seven simple steps.

Most of us consider Google to be the know-all and end-all for all research. That's not the case. There are cutting edge domains which require accessing specific search engines. These are where you'll find the latest journals and latest scientific papers. And even with Google, you are mostly presented with the websites which are optimised for search engines. Scientists and researchers aren't known for their SEO skills. So finding content written by researchers requires advanced Googling skills which you will find in this FastTrack.
