

In this chapter, you'll learn how to manually restore the previous version of the Registry on Windows 10 from an automated backup. Remember that if you don't do it right, altering system files can cause more problems with your installation. It's assumed that you know what you're doing and that you've already made a complete backup of your computer. At your own risk, try these actions.

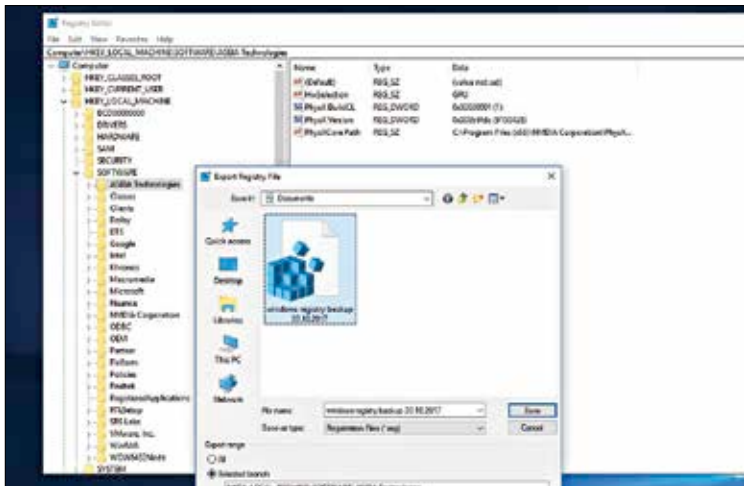

Backup Registry in Windows 11/10

It's a good idea to build a System Restore Point before you start. Before making any big modifications to your operating system, you should do this as a normal procedure.

Regedit or the Registry Editor in Windows can be used to save or backup your Registry. To open the Registry Editor, type 'regedit' into the Run box and press Enter.

Open Regedit, pick Computer, and right-click on it to back up the whole Registry. Select Export now. Give the file a name and save it in the desired location. The backup of the entire registry will be stored as a .reg file.

To back up a section of the Registry, go to the Registry key or Hive you want to back up. To save a copy, go to File > Export. You can save or Backup your Registry as a reg or binary or text or Win9x/NT4 format. Select your Export range and Save as type and click on Save to save the backup.

Partial backup of a registry
