

Most of the registry is backed up when you create a system restore point. There are some exceptions and they can be found at:

HKEY_LOCAL_MACHINE\System\ControlSet001\Control\BackupRestore\KeysNotToRestore

Automatic Windows Registry backups

Every time a system restore point is generated – whether automatically or manually by you – the Windows operating system stores the registry.

This is useful since the OS needs the old registry backup in order to produce a properly restored machine when you restore your computer to a previous point. It's not enough to just restore the files; it's just as critical, if not more so, to restore the backed-up registry. That is when and why Windows automatically saves the Registry.

Your system files, programmes, and registry settings will be affected by a System Restore. It can also make changes to your Windows computer's scripts, batch files, and other executable files. As a result, all changes made to these files will be undone. System Restore will not affect your Documents folder or personal files such as images, emails, or other documents, but it may cause files on your desktop to disappear. Before doing a System Restore, you may want to relocate your personal documents from your desktop to a safe location.

Restore Registry manually on Windows 10

To restore the Registry on Windows 10 manually, use these steps:

Advanced Startup options
