

Change “mtu>” to a number between 88 and 4294967295. Replace “your gateway>” with the Internet gateway that your network adapter uses. If you’re not sure what your gateway is, use the command line to look it up under “Default Gateway,” which appears under the network adapter you use to connect to the Internet.

When pingging, you’ll know you’ve gone too high if the response includes the following message: The packet must be fragmented, but the DF must be set.

You’ll be good as long as you choose a number that doesn’t require packet fragmentation. Choose the greatest amount feasible without causing packet fragmentation, and you’ll have the best MTU.

Now, to set this number, go to the following path in your registry:

```
\HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters\Interfaces\Interface ID
```

Replace “Interface ID” with your network interface’s GUID. Simply look at the information on the right side of the regedit window to see if the GUIDs shown under “Interfaces” match the details of the network interface you use to access to the Internet.

Once you’ve gotten to that interface, create a DWORD called “MTU” and set it to the number you get when you ping your gateway. That should solve a lot of problems.
