

When you're in Registry Editor, go to

```
HKEY_CLASSES_ROOT\CLSID\{018D5C66-4533-4307-9B53-224DE2ED1FE6}
```

Then, in the right pane, double-click the registry variable "System.IsPinnedToNameSpaceTree."

Change the value in the "Value data" box to "0" in the "Edit DWORD" window, then click OK.

Another registry key must be edited by 64-bit Windows 10 users (the majority will be – you can check this in your System Information next to System Type).

Go to

```
HKEY_CLASSES_ROOT\Wow6432Node\CLSID\{018D5C66-4533-4307-9B53-224DE2ED1FE6}
```

and do the same procedure as before, altering the value of "System.IsPinnedToNameSpaceTree" in the right-side pane to "0."

After you've learnt how to hide OneDrive from the File Explorer, click OK.

Delete Pagefile.sys at Shutdown

Pagefile.sys is a virtual RAM that Windows utilises to store programmes that aren't in use, allowing the actual RAM to be used more efficiently. The page file size is usually close to the amount of your actual RAM, thus depending on your RAM, it can take up a lot of space. If you set the pagefile to delete when the computer shuts down, you will save some hard drive space in exchange for a minor increase in shutdown time.

In Windows 10, you may get the system to destroy the pagefile.sys on shutdown in one of two ways.

You'll need to make adjustments to the Windows registry to accomplish this. Although this should be safe, you should back up your Windows 10 registry before proceeding.

When you set Windows to clear the pagefile on shutdown, it really overwrites the existing data in the pagefile with "zeroes." This makes recovering data from the pagefile nearly impossible. The time it takes to shut down your system may increase as a result of the rewriting process.

To have the pagefile deleted automatically when the computer is turned off, do the following.

By hitting Win+ R and typing regedit in the box, you may access the Windows 10 registry editor.
