

What is the registry?

A.K.A. the master control panel

The Windows Registry is a group of databases that store configuration information for Microsoft Windows operating systems. Much of the information and settings for software programs, hardware devices, user preferences, and operating-system configurations are stored in the Windows Registry.

When a new program is installed, for example, a new set of instructions and file references may be added to the registry in a specific location for the programme, as well as others who may interact with it, to refer to for more information such as where the files are located, which programme options to use, and so on. The registry can be compared to the DNA of the Windows operating system in many ways.
