

multiple servers. Network managers are finding it increasingly difficult to pinpoint the source of the attacks.

To avoid these DDoS attacks, administrators can:

- Use the Apache module mod_evasive to take evasive measures in the event of DoS/DDoS attacks. This module keeps track of the URLs that have been viewed via IP addresses in a dynamic database. When a single IP address sends too many requests in a short period of time, mod_evasive automatically bans that IP address from sending any more requests.
- Making use of Cloudflare's services. Between the server and the users who access the server, Cloudflare functions as a proxy server. It lowers the number of queries to the webserver by storing content in the cache and delivering it to users on demand.
- Filtering - Dedicated routers can be set up by administrators to identify connections from numerous sources and prevent them from slowing down the server.
- To protect the server from being hacked, the network administrator can send all traffic to a given site to an IP address that never exists.

4. Malware and Phishing Attacks

Malware is a type of harmful software that infects computers and steals personal information.
