

for that. We had to remove the laser from the robot, place it on the table, and begin testing. Varied voltages, and different power interruptions, all in an attempt to replicate the impact in a controlled environment. That's quite a bit of hardware contact. Many software developers dislike this kind of connection with the hardware. After all, they chose to work as software developers rather than hardware designers!!

Roboticians programming robots

As a result, roboticists, or persons who build robots, have been in charge of programming them. Although some of the roboticists were not directly involved in the creation of the robot, they have no qualms about delving into the hardware and attempting to resolve hardware issues in order to make their programmes work. But, let's face it, most roboticists can't programme as well as software developers. That is why robotics could greatly benefit from the influx of a large number of professional programmers.

The good news is that recruiting developers has never been easier. The Robot Operating System, or ROS, allows you to entirely separate the hardware from the software, allowing you to programme a robot just by understanding the robot's ROS API and having a simulation to test your code. You can forget about the hardware and focus on the software that makes the robot do what you want when you use the ROS API.
