```

You could use an ANSI console plugin (e.g. <http://www.mibai-nita.net/eclipse/>) to get rid of the “[Om]” characters in the output.

10. More eclipse goodies

Setup a file template that pre-formats whenever a new source or header file is created. The template could, for example, contain the license header, author name, and include guards (in case of a header file). To set up the templates, choose in the Preferences C/C++->Code Style->Code Templates. For example, to add the license header choose Files->C++ Source File->Default C++ source template and click on Edit... Paste the license header and click OK. From now on, all source files will automatically contain the license header.

Enable Doxygen with the project properties clicking on C/C++ General, enabling project-specific settings and selecting Doxygen as Documentation tool. This option automatically completes Doxygen style comments highlights them.

People that are used to the emacs key bindings can select emacs-style bindings in Windows->Preferences General->Keys and selecting the emacs Scheme. Also, other useful key bindings (e.g. make project) can easily be added.

To also index files that live outside the ROS tree (e.g. the boost include files) you can add them in project properties C/C++ General->Paths and Symbols.

The generated eclipse project also works great for Python code. Just install the PyDev plugin for syntax highlighting and code completion.

11. Auto Formatting

Eclipse also has extensive formatting configuration capabilities. To add the ROS formatting profile to Eclipse, perform the following steps:

- Download ROS_Format.xml to some location (versions: Indigo Kepler)
- Start Eclipse
- Select Window->Preferences->C/C++->Code Style
- Click Import...
