

- Select `ROS_format.xml` from the location used in step 1
- Click OK

As you edit a file, Eclipse should use this new profile to format your code following the ROS conventions. To reformat an entire file, select `Edit->Format`.

2. QtCreator

As QtCreator supports opening CMake projects out of the box, it does not require a setup procedure if started from a terminal. Note that this is absolutely crucial because otherwise the environment will not be set correctly and functionality related to `roscpp` or `catkin` will fail when running `cmake`.

Note that instead of starting QtCreator from a terminal, you can use the following modification to the desktop file which normally in Ubuntu resides in `/usr/share/applications` if you did a system-wide installation or in `~/.local/share/applications` if you installed it only for your user:

```
01 $ cat qtcreator.desktop [Desktop Entry]
02 Exec=bash -i -c qtcreator %F
03 Icon=qtcreator
04 Type=Application
05 Terminal=false
06 Name=Qt Creator
07 GenericName=Integrated Development Environment
08 MimeType=text/x-c++src;text/x-c++hdr;text/x-
  xsrc;application/x-designer;application/ vnd.nokia.
  qt.qmakeprofile;application/vnd.nokia.xml.qt.resource;
09 Categories=Qt;Development;IDE;
10 InitialPreference=9
```

In Ubuntu 13.04 and later, the third line must read:

```
1 Icon=QtProject-qtcreator
```

You should not try to generate this file yourself, but rather modify the file that was created when you installed QtCreator. Add `bash -i -c` in the `Exec` line and use it in your launcher. This will run your QtCreator in a shell which should source all required `setup.bash` files of your ROS installation and workspace. More about desktop files and their locations for Ubuntu can be found [here](#). Note also that the same trick can be used with `eclipse`.

If you are experiencing issues with the `qtcreator` package shipped by Ubuntu (or want to use a more up to date version of QtCreator) when opening the CMakeLists, then try installing QtCreator from Nokia's installer.
