

3. Enable Clang Code Model

Install recent clang (version ≥ 3.6) and this plugin. See the link for how to enable it. Although this may slow down your computer it is a very valuable tool to give you compiler warnings on-line.

4. Troubleshooting

When running `cmake` in QtCreator (when you open the package), check the output for error messages — they provide a clue on what is going wrong.

To remove cached/stored information for a project, remove the `CMakeLists.txt.user` (possibly with some trailing numbers) in your project and re-open the project. If that does not solve your problem, repeat (remove `CMakeLists.txt.user`) and additionally remove (or rather rename) the QtCreator configuration in `~/.config/QtProject` and `~/.local/share/ data/ QtProject/qtcreator` and try again.

5. Qt Creator Plugin for ROS

Please refer to instructions here. https://ros-industrial.github.io/ros_qtc_plugin/
