

Testing ROS

Make sure your robot works before taking it out for a spin

How can you put your ROS programming for a robot to the test? When creating a programme for a robot, you must ensure that it functions properly, which necessitates the use of tests. If you think you should test your code on the robot directly, reconsider. The final stage in any testing procedure is to test on a real robot.

Why not try it out on a real robot first? :

- Because you can harm someone or break the robot. Many things could go wrong with your programme when you start testing it, causing the robot to go insane and crash into anything. This is not a discussion about mobile apps!! We're talking about physical items that can be damaged or cause injury.
- Because testing on a robot takes significantly longer than testing on a local machine. To test on a real robot, you'll likely require a physical setup that you'll have to rebuild each time you test (because by doing
