

the test, the physical robot or things in the environment will change position and need to be reset).

For the design of a robot programme, testing with a real robot is required (at least at present). It is, however, the final step in the testing method.

The right process for robot development is as follows:

1. On your PC, you write the ROS programme.
2. You check if the programme works on your PC in some way.
3. You tweak the programme based on the test results until local testing works successfully.
4. You test your software on the real robot once you're satisfied it works correctly on your PC.
5. You'll notice that the findings on the real robot differ from your local tests. Then, in order to reflect the parts that were not working on the robot, you must edit the code as well as the local tests again.
6. Rep the entire testing process until it works on your local machine before moving on to the real robot.

You should never attempt your code on the robot until it works properly in the local test environment if you want to develop quickly and with as little fuss as possible.
