

Near: When Humans Transcend Biology,' futurist Ray Kurzweil claimed that computers would be as clever as humans by 2029. He also projected that by 2045, computers would be billions of times more powerful than human intelligence without the use of artificial intelligence. Bill Hibbard, a famous computer scientist at the University of Wisconsin-Madison in the United States, is sceptical of Kurzweil's predictions.

He believes AI will achieve human-level intelligence in the twenty-first century. Even by his most pessimistic estimate, he believes it will happen in the lifetimes of those who have already been born. Sceptics, such as Ernest Davis, a computer scientist at New York University, are on the other side of the debate from scientists like Hibbard. Davis acknowledges that AI might challenge even the best chess players, but it is still light years behind the average 7-year-old, who possesses qualities such as common sense, vision, language, and intuition about how the physical world works.

Taking over jobs

It's no secret that automation has risen dramatically in recent decades across all industries.
