

of long-term unemployment is increasing. Though a thorough examination would necessitate even more data, it is obvious that increased automation has had a negative impact on employment creation in the world's largest economy. Even more surprising is the fact that suicides and substance abuse-related illnesses have been on the rise among white middle-aged Americans for the past 25 years. Anne Case, the 2015 Nobel Memorial Prize in Economic Science laureate, made the discovery.

Rapid advancements in artificial intelligence and robotics are more than likely to be a major cause of economic deterioration for working-class Americans. Other variables, like as deregulation and globalisation, could be at play. However, in a poll done by the Chicago Initiative on Global Markets, 43 per cent of respondents believed that technological advancement was the main cause for the US's stagnating median earnings for more than a decade despite increased productivity. Only 28 per cent of those polled disagreed with the assertion. In addition, a 2015 research by the International Monetary Fund highlights technology advancement as a major cause of inequality in recent decades.

All of this portrays a less than a rosy picture: automation does actually eliminate many jobs in the economy that were previously performed by people, and there's no evidence that new technologies have created an equal number of employment opportunities to compensate. Despite the lack of exact data for nations like India, widespread automation is a reality in developing countries as well. However, whether developing countries like India would experience the same job crises as developed countries like the United States remains to be seen. However, given the state of affairs elsewhere, anxiety would not be unfounded.
