

End-to-end security

As robots grow more mobile, collaborative, edge-resident, and linked, the data-rich ecosystem they live in may become a target for cybercriminals looking to steal information. In addition to malware and cyber-ransom, companies may experience manufacturing delays as well as commercial interruptions. In addition, cyberattacks on sophisticated robotic systems raise fundamental questions about the physical safety of those systems.

What is the solution? A thorough, end-to-end strategy for cybersecurity is recommended. To identify potential access points and harden vulnerable targets, system integrators must thoroughly understand the machines they are installing as well as the general environment in which they will be operating. The robot operator's information technology staff must be constantly involved, actively monitoring risks and continuously updating security measures.
