

Security must also extend beyond the end of a gadget's useful life, preventing the prospect of a device having an afterlife in the hands of evil individuals. On occasion, out-of-date edge devices can be found on eBay, where hackers can purchase them for a low price and subsequently reverse engineer them. Consequently, it is critical to decommission devices using tamper-proofing techniques or erasing sensitive software – making it hard to reverse engineer – before they may be used again.

Cost

Advanced technology and new business models are pushing economies of scale in robotics, which is encouraging given that cost is the number one hurdle for prospects for industrial robots, according to a survey conducted by the Robotics Industry Association. With the rise of Robots-as-a-Service (RaaS), more manufacturers are transitioning to the role of service providers, allowing customers to adjust the number of operational units to meet demand as the need grows.

Artificial intelligence and machine learning algorithms have become more efficient, making it easier to programme robots, develop creative use cases, and minimise energy consumption and consumption requirements.

RaaS and leasing are emerging business concepts that help customers cut costs by reducing barriers to automating their processes with robots. The development of appealing use-case scenarios by robot developers and integrators can also make it easier for potential end-users to conceive compelling use-case situations before making a final investment decision.
