

The advancements in computing, data transfer, and storage allow us to do more with less. Artificial intelligence and machine learning algorithms have become more efficient, making it easier to programme robots, develop creative use cases, and minimise energy consumption and consumption requirements. As more and more capabilities become accessible at lower processing prices, Moore's law continues to hold true in terms of computing costs, despite the fact that some believe it no longer applies to the number of transistors in use.

Conclusion

Sensor technology, computing power, and edge processing have advanced to unprecedented levels, and this has the potential to provide robots with robust artificial intelligence capabilities. However, this is contingent on secure, but flexible connectivity and interoperability among all ecosystem participants. Automated systems must be able to connect quickly and easily with other robots, as well as with a wide range of Internet of Things (IoT), edge, cloud, and analytical tools, among other devices.

To date, the robotics and Internet of Things communities have been motivated by a variety of goals that are very connected. When it comes to pervasive sensing, monitoring, and tracking, the Internet of Things
