- Cloud version available: Yes

MongoDB is the developer's favourite choice when it comes to handling unstructured data. So, a lot of the new generation applications that deal with ingesting ridiculous amounts of unstructured data tend to use MongoDB for that explicit purpose. Another key feature that helps in its popularity is the fact that it can handle unstructured data and also be fast at executing queries. However, if you end up requiring complex transactions, then MongoDB makes way for some of the other database software out there. So, in the end, it's mostly used for ingesting unstructured data.

MongoDB is not open source, rather it is termed as “source available”. This means that the source code can be viewed and sometimes modified but with significant oversight. It is generally deemed non-free for large-scale applications. They offer a free tier that can be used by anyone for perpetuity but you are given limited resources. Therefore, you can't develop large scale applications on the free tier. **d**
