

```

Program.cs
1  using System;
2
3  namespace DotnetBot {
4
5      public static class Program {
6
7          public static void Main(string[] args) {
8
9              string message = "";
10             if (args.Length < 1) {
11                 message = "Welcome to .NET Core!";
12             }
13             else {
14                 foreach (string item in args) {
15                     message += item;
16                 }
17             }
18         }
19     }
20 }

```

Sample C# code

- C# has a strict Boolean data variable type, such as bool. On the other hand, C++ bool variable types can be returned as integers or pointers. This is done to avoid common programming errors.
- C# uses a garbage collector to automatically manage inaccessible object memory. This will eliminate developer concerns as well as memory leaks.
- C# type is safer than C++. This language also has safe default conversions only (for example, integer widening). These are implemented when the compilation is carried out (or at runtime)
- No implicit conversions between enumeration members, Booleans, integers (apart from 0) can be converted to an enumerated type. User-defined conversions have to be specified as implicit or explicit. However in C++, there are default implicit conversion operators and copy constructors.
