

To create a new project, go to the directory you want the project to be in and select `cargo new fizzbuzz`. This will instruct Rust's build manager to create a new project. Once you do that, go to the `/src` folder and open up `main.rs`. You can now write the code and run it to see how it works.

Basic Code

Here's some basic code to practise:

Hello World

```
fn main() {
    // Statements here are executed when the compiled
    // binary is called
    // Print text to the console
    println!("Hello World!");
}
```

Get the largest string

```
fn largest<'a>(str1:&'a str, str2:&'a str) -> &'a str {
    if str1.len() > str2.len(){
        str1
    } else {str2}}
fn main() {
    let str1 = "Hello";
    let str2 = "linuxhint";
    let result = largest(str1, str2);
    println!("Largest: {}", result);
}
```

Primitives

```
fn main() {
    // Variables can be type annotated.
    let logical: bool = true;
    let a_float: f64 = 1.0; // Regular annotation
    let an_integer = 5i32; // Suffix annotation
    // Or a default will be used.
    let default_float = 3.0; // `f64`
    let default_integer = 7; // `i32`
    // A type can also be inferred from context
    let mut inferred_type = 12; // Type i64 is inferred
    // from another line
}
```
