

Recording

Timing and sync

These are the settings for the number of frames per second. The following frame rates are the most common ones used for filming and broadcasting on television:

- 24 for most cinematic work
- 25 for PAL and European broadcast
- 29.97d for NTSC and American broadcast
- 48, 50 and 60 are more exotic rates that can be used for aesthetics and are common for the action cam shots synonymous with GoPros.

If you get these wrong, your SMPTE time code will pretty much be rendered useless, and you won't be able to achieve any kind of sync.

Sample rates and bit depth

The amount of samples collected per second, in addition to the overall resolution and dynamic range of your project, will be determined by these.

In production and mixdown environments, the bit depth of 24-bit is typically used as the standard. The content will not be dithered down to 16 bits unless it is specifically required for a media.

The sampling rate for video has traditionally been set at 48 KHz, while 96 KHz and 192 KHz are starting to become increasingly commonplace in the industry. While there is no inherent problem with employing sample rates that
