

outperforming DALL-E 2, which scored 10.39. However, the Stable Diffusion team has not yet published benchmark scores for comparison with other models. In the original Latent Diffusion paper, the Latent Diffusion Model (LDM) achieved a 12.63 FID score using the 56×256 -sized MS-COCO dataset with 250 DDIM steps.

How is stable diffusion being regulated?

The ethical, moral, and legal concerns surrounding the misuse of AI devices have been widely discussed, and the use of Stable Diffusion raises particular issues due to its ability to generate a wider range of images, including those of real people, which is prohibited in comparable models such as DALL-E 2.

To address these concerns, Stability.ai has emphasized the importance of ethical and legal use of the model and has released it under the Creative ML OpenRAI-M license, which allows for both commercial and non-commercial usage. The license requires users to self-regulate their conduct and prohibits the use of the model or its derivatives in ways that harm minors, defame anyone, discriminate against individuals or groups, or exploit the vulnerabilities of specific groups. However, the license itself does not have any enforcement mechanisms, and Stable Diffusion's Safety Classifier tool, which is designed to remove undesirable outputs, can be disabled by users.

The lack of specific laws regulating the use and misuse of AI models in many countries, including Australia, leaves technology like Stable Diffusion vulnerable to exploitation by bad actors.
