

generated artwork? Is it the person who programmed the AI, the person who inputted the prompts, or the AI itself? This question is still largely unresolved and has implications for copyright and intellectual property law.

There are also concerns about the potential impact of AI on the job market for human artists. As AI becomes more advanced, it may be able to create art that is indistinguishable from that of human artists, potentially displacing them from their careers.

Finally, there are ethical concerns around the use of AI in art. Some worry that the technology could be used to manipulate people's emotions or spread propaganda through art in a way that is difficult to detect or combat.

Overall, the controversy surrounding AI-generated art reflects the broader societal questions that arise with any new technological advancement. While there are certainly concerns to be addressed, there is also great potential for AI to revolutionize the world of art and create entirely new forms of creative expression.

The rapid advancement of generative AI technology has outpaced our ability to anticipate future risks. To ensure long-term, sustainable market growth, we need to address critical ethical questions on a global scale. First, it is important to understand how foundation models such as GPT-3 and DALLÉ-2 function. These deep-learning tools aim to create more realistic images, text, and speech by surpassing other models. Companies such as OpenAI and Midjourney train their AI on vast datasets from billions of users to produce better and more sophisticated outputs.

While there are many positive applications for these tools, we cannot ignore the possibility of exploitation and the legal uncertainties that this technology presents. As a society, we must be vigilant in recognizing these risks.

Copyright

Is it appropriate for a program to claim authorship of its output even though it is derived from multiple inputs? This is a debated issue with legal implications. In the US and Europe, patent offices have denied patent applications where AI was cited as the inventor, ruling that non-human inventors are not eligible for legal recognition. However, South Africa and Australia have recognized AI as inventors on patent applications. Furthermore, a New York-based artist received the first US copyright for a graphic novel created with AI-generated artwork.

On one side of the debate, it is argued that generative AI is merely a tool for human creators, akin to using Photoshop to modify or create an image.
