

On the other side, some believe that the rights to AI and its creations should belong to the AI itself and its developers. While developers may understandably desire content creation rights for their successful AI models, this approach is unlikely to be successful in the long term.

Moreover, it is crucial to recognize that these AI models are reactive, meaning they can only produce outputs based on the information they are given. These place control firmly in the hands of humans. Even AI models that are allowed to refine themselves are ultimately driven by the data provided by humans, making it impossible for them to be truly original creators.

Deepfakes

Managing the ethical challenges posed by deep fakes, AI-generated content that mimics human creators, and intellectual property is a complex issue. The potential harm caused by the spread of fake videos, propaganda, and explicit content raises concerns about privacy and consent. Additionally, the possibility that AI may be able to create content in someone's style, with or without their permission, could put people out of work.

Furthermore, generative AI models often exhibit biases based on the data they are trained on, creating additional ethical challenges. The data used for training is someone else's intellectual property, and their consent may not have been obtained for its use in creating AI models. Currently, there are no adequate laws in place to address these issues surrounding AI outputs. However, if AI is viewed simply as a tool, then the responsibility for the content created by the system lies with the human creators, not the tool itself.

Thus, the ethical debate around AI-generated content must focus on the people who use the tool and the claims made about the tool's capabilities.
