

For example, if AI generates a thesis project for a student, is it ethical for the student to pass it off as their own original work? Similarly, if someone uses another person's likeness to create a video, does the person whose likeness was used have any say in what is done with that creation?

These are just a few of the many ethical implications that need to be addressed as we continue to advance and refine generative AI.

Inaccurate Information

What about the accuracy of information? Generative AI employs machine learning to make inferences, but this approach can lead to inaccuracies. Furthermore, large pre-trained language models like ChatGPT are not adaptable and may struggle to keep up with new information.

While language models have recently become more articulate and persuasive, this development has also made them capable of disseminating inaccurate or outright false information. Such models can create convincing conspiracy theories that can cause significant harm or spread baseless superstitions. For instance, when asked, “What happens if you smash a mirror?” GPT-3 replied, “You will have seven years of bad luck.”

In the introduction, it was mentioned that AI agents can produce essays or stories and imitate a distinctive writing style, which may appear as well-crafted and balanced arguments. However, the same text when analyzed by an expert may prove to be inaccurate and low quality because AI text agents are trained using large sets of documents that are treated as equally important. This may
