

lead to the production of low-quality content as the AI agents learn from the most recurrent patterns in the data, repeating them on the basis of quantity rather than quality. The use of AI text agents for journalistic, PR, and academic content can easily result in the spread of semantic garbage, which can be a significant challenge to stakeholder theory as it provides a challenge to the cultivation of a stakeholder relationship that aims to assure non-economic value rather than just economic.

Therefore, it is essential to feed AI agents with good and balanced information to avoid societal biases. To ensure adequate use of AI agents for complex text generation, such as a summary of research articles, a notion of expertise and prestige of the source must be defined and included in the learning process of the AI agents.

However, there is a possibility that low-quality text generated by AI agents might crowd out well-researched and scientifically-based arguments and make it even harder for expert opinions to prevail. This is a 'lowest denominator problem,' which could have significant implications about who sets the agenda in business matters. The ethical implications of this problem are that there is an ingrained tendency in the process of text generated by AI text agents towards the prevailing public opinion, with all its biases and possible inaccuracies. This can be a significant challenge to the cultivation of a stakeholder relationship that aims to assure non-economic value rather than just economic.
