

in either a positive or negative light, making the potential for greenwashing and the spread of disinformation much higher. This phenomenon can further erode the trust that stakeholders have in what corporations say about themselves, especially when it comes to sensitive issues such as vaccine production and distribution.

Therefore, there is a need to address the “fake agenda-setting problem” caused by AI-generated disinformation. In the discussion section, potential solutions and strategies could be explored to address this issue.

Societal Biases

Finally, another ethical conundrum lies in the fact that we may see an increase in societal biases being perpetuated. Large language models have revolutionized human-like speech and text, but there is mounting evidence that more

sophisticated systems tend to internalize underlying social biases from their training data. Such AI biases can include sexism, racism, or ableism prevalent within online communities.

For instance, a 280 billion parameter model developed recently showed a significant 29% increase in toxicity levels compared to a 117 million parameter model developed in 2018. As these systems become even more powerful tools for AI research and development, the potential for increased bias risks becomes more apparent.
