

creates a mediation problem that can cause ethical issues in the business world, including the potential for misunderstanding and blurred understanding of who is communicating with whom. The moral foundations within arguments developed by AI text agents must also be considered, as the agents may hold their own morality and mediate intended messages. Responsibility for aligning messages with specific moral foundations must be placed not only on businesses and manufacturers but also on stakeholders involved in the agent's use. Failure to do so could result in stakeholders making decisions based on unintended moral components, and machine-based agendas could blur the understanding of how public agendas are built.

How can these challenges be mitigated?

In the preceding section, three challenges that can be caused by new sophisticated AI agents were identified: (1) the fake agenda problem, (2) the inaccurate content problem, and (3) the communication gap problem. Here, we explore potential ways to address these problems.

There are two potential approaches: controlling the AI agents themselves or restricting their use by different organizations. To control the agents, designers could include an “honesty” program in their products to prevent their AI agents from lying or misleading, as described in Isaac Asimov's (1950) collection of short stories, *I, Robot*. Asimov argued that robots should be programmed to avoid harming humans, and this should be incorporated into their design.

Similarly, AI agents could be designed with a “judgment” system to learn from existing material, avoiding or minimizing the lowest denominator problem. However, this type of control, where a guidance system is implemented to regulate the sources from which an AI agent learns, has its risks. There is a fine line between excluding unqualified opinions and censorship, and creating guidelines or restrictions raises the question of who should be responsible for them. An independent organization of experts in the field, appointed by the government, could be the most suitable candidate to navigate the middle ground between excessive political and corporate influence.

Developing an AI agent that avoids polarizing and radicalizing discourse could be a start to addressing the fake news problem, but it would not be an easy task. Surveillance capitalism, which allows online search firms to accumulate personal information, enables AI agents to misinform individuals if they are instructed to do so. The risk of fake news content spreading disinformation and manipulating public opinion is quite real, as seen during the
