

Next, download Stable Diffusion from GitHub by clicking on the green “Code” button and selecting “Download ZIP,” or by using this direct download link.

Now, let’s create a few folders where Stable Diffusion’s files can be unpacked. Open the Start menu and type “miniconda3” into the search bar, then click “Open” or press Enter. Using the command line, create a folder named “stable-diffusion” by copying and pasting the following code block into the Miniconda3 window, then pressing Enter:

- `cd C:/`
- `mkdir stable-diffusion`
- `cd stable-diffusion`

Remember to hit Enter after pasting the code block into the terminal. Keep the Miniconda3 window open as it will be needed again shortly.

To install Stable Diffusion, follow these steps:

1. Download the latest checkpoint from the Stable Diffusion website. Note that version 1.4 is nearly 5GB, so it may take some time. You’ll need to create an account to download the checkpoint, but only a name and email address are required.
2. Click “sd-v1-4.ckpt” to start the download. You can also download “sd-v1-4-full-ema.ckpt,” which is about twice the size and may provide better results.
3. Download Stable Diffusion from GitHub by clicking the green “Code” button and selecting “Download ZIP,” or by using the direct download link.
4. Open the downloaded ZIP file in your preferred file archiving program, or use Windows to open it directly. Keep the ZIP file open in one window and open another File Explorer window to navigate to the “C:\stable-diffusion” folder that you just created. Drag and drop the “stable-diffusion-main” folder from the ZIP file into the “stable-diffusion” folder.
5. Go back to Miniconda3 and copy and paste the following commands into the window:

- `cd C:\stable-diffusion\stable-diffusion-main`
- `conda env create -f environment.yaml`
- `conda activate ldm`
- `mkdir models\ldm\stable-diffusion-v1`

Don’t interrupt the process, as some of the files may be larger than a gigabyte and take some time to download. If you accidentally interrupt the process, delete the “ldm” folder in “C:\Users(Your User Account).conda\envs” and run “conda env create -f environment.yaml” again.
