

```
"prompt:" "Futuristic architectures  
with planets in the  
background."
```

```
{  
  "prompt:" "View of a cyberpunk  
city."  
}
```

customize the results further. To get a comprehensive list of all arguments, you can run the command “python scripts/txt2img.py --help”.

Getting great results with Stable Diffusion requires a lot of experimentation, but it can also be a lot of fun. Make sure to document the arguments and descriptions that yield desirable outcomes. Alternatively, you can join online communities like Reddit, where people exchange pictures and prompts that generated them.

How to write a script?

Getting a good prompt is the most challenging aspect of using Stable Diffusion, but modifying a few other settings can drastically alter the results you get.

1. **CFG:** Controls the extent to which Stable Diffusion follows your prompt. Increasing this number results in more adherence to the prompt, while decreasing it gives the AI more flexibility. Experiment with this setting first.
2. **Sampling Method:** Determines how the AI transforms noise into recognizable shapes. Try several of these methods, such as Euler_a, k_LMS, and PLMS, as they are popular choices.
3. **Sampling Steps:** Specifies how many times the AI will sample an image before providing a final output. While 30 steps may produce good results, sometimes you may need to use 50 or 80 steps. Results usually don't improve beyond 150 steps, so it's best to start with fewer steps and gradually increase them.
