

However, if you want to animate an object that moves from point A to point B, this would require a significant amount of tweaking prompts and settings, as well as sifting through a large amount of output to find the best frames and put them in the correct order. At this point, it may be more efficient to animate manually using Adobe Illustrator.

Nonetheless, with a basic Stable Diffusion setup and another tool for stitching the frames together, you can create cool and simple animations. Deforum is a project that uses Stable Diffusion to create morphing animations that are quite interesting. This project generates an MP4 video, so no external tools are needed, and even lets you add audio. We will provide an overview of both methods.

## How to Animate an Image with Inpaint?

With Inpaint, a tool within img2img, you can create multiple variations of a selected part of an image and use them to generate a GIF or video animation. Here are the steps to get started:

### Step 1: Choose an Image and Create a Prompt

First, select an image that you want to animate and upload it to Inpaint within img2img. If you don't have an image, you can either generate one using Stable Diffusion or use one of your own photographs or drawings.

If you're using an image that wasn't generated with Stable Diffusion, you'll need to create a prompt for generating variations. To do this, click "Interrogate CLIP" at the top of the Img2Img page. This will create a starter prompt based on what Stable Diffusion thinks is in the image. You can then add any additional details to complete the prompt.
