

Step 2: Mask the Parts to Animate Using InPaint

After importing your image and prompt to the Inpaint tool, use the paintbrush feature to mask or cover the parts of the image you want to animate while leaving the parts you want to remain static uncovered.

For instance, if you want to animate the movement of a person in the picture, you will cover up everything else but that person using the paintbrush. In another example, if you want to animate the flame on a candle, you will mask every other part of the image except the candle flame.

It is important to avoid getting too close to the object while masking it. For instance, if you are masking a robot, leave some cushion around it to prevent Stable Diffusion from adding unwanted appendages or objects to the robot.

Step 3: Create Your Animation Frames

Once you have masked the parts of your image that you want to animate, it's time to generate your animation frames using img2img. However, before you proceed, you need to ensure that the tool has the right settings for your project. Here's a rundown of the various settings, along with their explanations and suggestions on whether or not to adjust them:

1. **Mask Mode: Inpaint Masked** – This setting ensures that Stable Diffusion modifies only the covered areas and not the other way around. If you wish to modify the unmasked part instead, change it to “Inpaint Not Masked.”
