

2. **Masked Content: Original** – This setting ensures that Stable Diffusion considers the existing image when generating variations. Otherwise, it will consider the masked content a blank or randomized canvas.
3. **Inpaint Area: Whole Picture** – This setting forces Stable Diffusion to generate a whole new image for each frame before integrating it with the original image. Changing to “Only Masked” might speed up generation but may also give you worse results.
4. **Sampling Method: DPM++ SDE** – We used this sampling method for generating our original image, and we suggest sticking with it to ensure a consistent look. If you are unsure what to use, “Euler a” is a good all-around choice.
5. **Batch Count: 60** – This setting determines how many images you want to generate. You may need more or fewer frames depending on how long you want your animation sequence to be.
6. **CFG Scale: 5** – This setting determines how much creative freedom Stable Diffusion has. The higher the number, the more closely Stable Diffusion will follow your prompt. Increasing it requires a well-crafted prompt.
7. **Denoising Strength: 0.3** – This setting determines how much Stable Diffusion will change the original image. It’s possibly the most important setting for this project. You should keep it around 0.2 or 0.3 to avoid ruining the animation with too much frame-to-frame change.
8. **Seed: -1** – This setting tells Stable Diffusion to start with a random seed.
