

We recommend not reusing the seed from your original image to get more variation.

After adjusting your settings, click on “Generate” and wait while Stable Diffusion generates your animation frames. You can find the frames in the /outputs/img2img-images folder of your Stable Diffusion directory. If you are not satisfied with the results, tweak your settings (starting with denoising strength and sampling steps) and try again.

Step 4: Upscale Frames in Batch (Optional)

If you plan to make a high-definition video, you’ll need to upscale your generated frames to the desired resolution. Begin by clicking “Send to Extras.”

Switch to the “Batch Process” tab inside Extras. Adjust the “Resize” scale to specify the number of times you want the frames to be resized. For example, setting it to 2 will increase 512x512 images to 1024x1024. Alternatively, select “Scale to” and set a particular resolution.

Choose the upscaler of your choice by setting “Upscaler 1.” We recommend using R-ESRGAN 4x+ as it gave good results, but you can experiment to find out which one works best for your images.

Once you’ve made your selections, click “Generate,” and Stable Diffusion will provide you with a higher-resolution version of each frame, saved in the /outputs/extras folder.

Step 5: Create Your Final Animation

After generating your frames, it’s time to assemble them into an animation. There are various tools to do this, such as free online websites like Ezgif and Flixier, which provide easy-to-use and comprehensive controls. However, be cautious about uploading content you’re not comfortable sharing with the public, as these websites can access everything you upload. In this tutorial, we will demonstrate how to use the free offline photo editing software GIMP to create a GIF. For video files, you can use Kdenlive or a similar video editor, but
