

prompt will be used from frame 0 and all frames after it, the second prompt will start generating variations from frame 40, and the third prompt from frame 80. You can add as many prompt changes as you wish and adjust the maximum frame limit on the Keyframes tab as necessary.

Step 3: Adjust Deforum Settings

Let's go through some of the Deforum settings to get started. Begin by accessing the "Run" tab, which contains most of the standard Stable Diffusion settings. You can rename the batch, select the seed you want to use (we're sticking with the robot seed), and choose the sampler you want to use.

In the Keyframes tab, you can modify the motion of the animation's "camera." It is set to zoom at intervals by default, but we want to incorporate a vertical "pan" movement. As a result, we'll add 0:(-2), 100:(4) to

the "Translation Y" frame. This instructs Deforum to consider the first frame as being at pixel -2 on the Y axis, then to move to pixel 4 by frame 100. This will result in a gentle upward pan as the animation progresses.

In the Output tab, you can tick the "Make GIF" box, which will create a GIF file in addition to the MPEG video file. If you have audio, you can add it using the "Add Soundtrack" and "Soundtrack Path" settings.

Step 4: Create Your Video

Now it's time to create your video! Click the "Generate" button and sit back while Deforum creates and stitches together multiple frames. The process might take a while, so take a break and grab some coffee while you wait.

Once it's done, you can find the MPEG file, the GIF version, and every individual frame, along with a list of the settings you used under the batch name in your /outputs/img2img-images directory.

What are the PC Hardware Requirements for Stable Diffusion?

Stable Diffusion primarily relies on the graphics card (GPU) for its processing
