

“the problems of discipline exclusivity and people not being able to talk across disciplines or understand each other and those barriers have really been broken down by AI.”

Biases in research

While some participants from the aforementioned study viewed impact as a positive outcome, others expressed concerns about using AI to deliver impact activities and its potential impact on inequalities and biases. One participant shared an example of AI being used to raise awareness about HIV among high-risk populations, where the AI selects peer leaders within communities of homeless youth to support awareness building. However, some participants expressed concerns about “the potential intensification of existing inequalities”. Others shared worries about the increasing inequalities in society that AI could exacerbate, with one participant stating that AI is contributing to “dramatically accelerating inequalities”.

Specifically, they were concerned that AI has the potential to worsen existing social inequalities among young people of different genders, races, and socioeconomic statuses. One participant referred to AI as a “mirror of ourselves”, reflecting biases present in our society. The bias in AI is often due to biased data input, which results from human decisions in data curation and collection. To address this issue, several interviewees suggested prioritizing research on explainability, trust, and fairness in
