

rather than a broad, general approach. Nevertheless, a new era of scientific generalists could foster a renaissance in science and encourage an interdisciplinary dialogue. It is important to be mindful of disciplinary differences and potential disadvantages, particularly for fields such as Humanities and early career researchers, where adequate support and career opportunities may be undermined. Naming AI as a component of ubiquitous computing systems, such as web search and recommender systems, can be useful, as it reinforces the positive impact of AI in speeding up and making research more efficient.

However, it is important to be mindful of the negative consequences of performativity culture on individuals and groups. With responsible implementation, AI has the potential to enhance meaningful relationships within and between disciplines, as well as between academia and the public.

Interpretations of Human Emotion

The idea that a researcher's job is primarily data processing oversimplifies the academic role and reduces humans and organizations to mere data points. Humans are agents of meaning and scientific articles are not simply processed but interpreted and experienced. Therefore, the assumption that Science is solely about creating data is incomplete, as creativity and human understanding play a crucial role. Although interviewees mentioned how AI can relieve them of certain tasks, they also cautioned against the loss of critical
