

which systems to use and implement with care, taking into account the lack of neutrality in technology. Additionally, future research, anticipatory governance, and forecasting are necessary to develop a supportive and beneficial research culture that includes AI.

The application of AI in problem-solving is limited to data-in-data-out processes, representing only a small part of human experience. Our interviewees have expressed concerns about the potential loss of human involvement in future research. The discussions have touched upon issues of interpretation, fairness, and care for colleagues, which are integral to research quality. Research is driven by curiosity, exploration, and fascination, and should not be reduced to measurable products. The danger lies in prioritizing measurable outcomes over human considerations. Therefore, we must decide how far AI should be incorporated into research and for what purpose. Currently, there is no clear strategy for AI adoption, resulting in mixed reactions from researchers. The lack of information and best practices has led to both excitement and fear. We need to shift our focus away from increasing productivity and ask more important questions about our future goals. It is crucial to have a realistic view of what AI can and cannot do and to detach effective research practices from measured outcomes.

Challenges for researchers

The integration of AI into research poses a challenge for researchers, as its benefits depend on human decisions and actions, as well as the research culture
